Using Prescription Stimulants to Study

- ‘Study Drugs’ is a term used to refer to the misuse of prescription medications that are prescribed to treat Attention Deficit Hyperactivity Disorder, or ADHD.

- The most common medications prescribed for ADHD are Adderal, Ritalin, Concerta, Focalin, and Dexedrine. These medications should be used according to doctor’s orders ONLY.

- Misuse of prescription drugs includes: using higher quantities or taking more frequently than prescribed, taking other people’s medication, altering the medication’s delivery method (e.g. crushing & snorting), using a prescription in order to get high.

How Prescription Stimulants Effect the Body

- They act as stimulants by speeding up the activity of your nervous system.

- These prescription medications provide symptom management for individuals with ADHD.

- Taking without a prescription can have adverse side effects, such as: irregular heartbeat, problems with circulation, psychosis, severe depression, increased aggression, restlessness, & extreme agitation.

- Using prescription stimulants with alcohol can increase the chances of alcohol poisoning by creating a false sense of sobriety so that you drink more than you normally would.

Performing at Your Peak

It may seem obvious, but a good night’s sleep means a lot. Research shows that sleep plays a critical role in immune function, metabolism, memory, learning and other vital functions.

- Not getting enough sleep — whether for one night or over the course of weeks has a significant effect on our ability to function and can have both short and long term consequences.
- Short Term: Lack of adequate sleep can affect judgment, concentration, mood, logical reasoning, ability to learn and retain information.
- Long Term: Chronic sleep deprivation can lead to a multitude of health problems including diabetes, cardiovascular disease, obesity, and even early mortality.

How can Alcohol and other Drugs Impact Sleep and Performance?

There are two kinds of sleep: Rapid Eye Movement (REM) sleep & Non-REM sleep.

- REM sleep only makes up about 20-25% of the total time spent sleeping, but is the most important kind of sleep a person gets during the night.

- REM sleep allows you to wake up feeling rested

- Alcohol and marijuana use can both lead to reduced REM sleep, which can cause: Memory loss, poor sleep quality, and interrupted sleep patterns; all of which can lead to poor performance.

- Other drugs / substances can also interfere with sleep on the day of use, as well as several days after the fact (e.g. caffeine, prescription medication, amphetamines, benzodiazepines & cocaine).
